10 September 2017

The present investigation was carried out at Horticultural Research Station, Mondouri, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, Nadia, West Bengal, India during spring summer seasons of 2015, 2016 and 2017 in a Randomized Block Design with three replications. The morphological characterization was done as per minimal descriptors of NBPGR developed for bottle gourd. The results revealed that the greatest diversity was observed in fruit characters especially fruit shape and fruit colour among the genotypes for various characters studied. Analysis of variance revealed significant differences among genotypes for all the characters. In general PCV was marginally higher than the corresponding GCV indicated the less influence of environment in the expression of the characters under study. High heritability coupled with high genetic advance as percentage of mean was observed for vine length, number of primary branches, days to first male flower appearance, days to first female flower appearance, days to first harvest, number of fruits per plant, average fruit weight, fruit length, fruit width, fruit yield per plant, sex ratio, seed number per fruit, 100 seed weight, TSS of the pulp, total sugar content and ascorbic acid content of the pulp indicated that these characters were mainly controlled by additive gene effects and thus selection may be effective.

### Introduction

Cucurbitaceous vegetables are the largest family consisting of maximum number of edible species in vegetable kingdom. Bottle gourd is botanically known as *Lagenaria siceraria* (Mol.) Standley. and its chromosome number is  $2n = 22$  is one such important vegetable of this family with high genetic diversity for fruit shape and other fruit characteristics, resulting in a variety of uses (Bisognin, 2002). Telangana region in India is endowed with a rich variability of bottle gourd, especially with regard to fruit characteristics (Sivaraj and Pandravada, 2005). Morphological characters are useful

for characterizing genotypes against highly heritable and stable traits. Further, association of any morphological character with desirable traits or yield components serves as a phenotypic marker in the selection process. The objective of this study is to determine the magnitude of genetic variability, heritability and genetic advance that could be realized through selection. The information obtained from this study would be helpful to specify certain traits that could be used as selection indices for identifications of potentially high yielding bottle gourd genotypes.

## Materials and Methods

The experimental material consisted of twenty one genotypes were laid out in a Randomized Block Design (RBD) with three replications at Horticultural Research Station, Mondouri, Bidhan Chandra Krishi Viswavidyalaya, Mohanpur, Nadia, West Bengal, India during spring summer seasons of 2015, 2016 and 2017. Each genotype was represented by a double row plot of 5 m length with 10 plants sown at a distance of 3 m between rows and 1 m between plants. Observations were recorded from five randomly selected plants for all the quantitative characters except days to first male flower appearance, days to first female flower appearance and 100 seed weight. Data on qualitative parameters was recorded on whole plot basis. The data on qualitative and quantitative characters were recorded as per minimal descriptors of NBPGR developed for bottle gourd. TSS content of the pulp was determined by an ERMA Hand Refractometer. The sugar content of the pulp was estimated by following anthrone method as per Dubois *et al.* (1956). Ascorbic acid content of the pulp was determined by 2, 6-dichlorophenol indophenol titration method (Ranganna, 1986).

For statistical analysis, Analysis of variance was done based on RBD as suggested by Snedecor and Cochran (1937) and reviewed by Panse and Sukhatme (1967) for each of the characters separately. Genetic parameters, genotypic, environmental and phenotypic coefficients of variation (expressed in percentage) were calculated by using the formula given by Burton (1952). Heritability in broad sense was determined according to the methodology given by Allard (1960). The estimate of the expected genetic advance (GA) expressed as a percentage of the mean was computed by the formula given by Johnson *et al.* (1955).

## Results and Discussion

The results on morphological characters of bottle gourd are presented in table 1. The qualitative characters including fruit stem shape, tendril, tendril branching, leaf margin, leaf shape, sex type and flower colour were constant for all accessions. This was consistent with the results of Huh *et al.* (2008) on Korean and Turkish watermelon populations and Aruah *et al.* (2010) on variations among some Nigerian *Cucurbita* landraces. The greatest diversity was observed in fruit characters especially fruit shape, fruit colour and inflorescence type. This concurs to the findings of Bisognin (2002) who reported that cucurbits are very similar in above ground development but have high genetic diversity for fruit shape and other fruit characteristics.

The analyses of variance for sixteen characters of twenty one genotypes of bottle gourd are presented in table 2. Highly significant differences were observed among the genotypes for all the characters indicating presence of large amount of variability in all the characters studied. These findings are in general agreement with the findings of Pandit *et al.* (2009) and Bhardwaj *et al.* (2013) in bottle gourd.

The phenotypic variance ( $\sigma^2_p$ ) and phenotypic coefficient of variation (PCV) were slightly higher than corresponding genotypic variance ( $\sigma^2_g$ ) and genotypic coefficient of variation (GCV) for most of the characters indicated the presence of less environmental effect upon the concerned characters. The genetic parameters *viz.*, genotypic and phenotypic coefficients of variation, heritability in broad sense and genetic advance along with mean and range of different characters are presented in table 3. High magnitude of GCV as well as PCV were recorded for traits *viz.*, fruit length (38.07 and 40.34), fruit width (37.11 and 37.92), vine length (30.26 and 30.85), fruit

yield per plant (25.50 and 26.00), sex ratio (23.16 and 23.96), number of fruits per plant (22.39 and 23.23), number of primary branches (21.78 and 22.71), seed number per fruit (20.85 and 21.23) and average fruit weight (20.57 and 21.04). Moderate GCV and PCV were recorded for TSS of the pulp (14.12 and 15.21), 100 seed weight (13.70 and 13.87), total sugar content of the pulp (13.35 and 13.75), Ascorbic acid content of the pulp (12.55 and 12.64), days to first harvest (11.57 and 11.94), days to first male flower appearance (10.69 and 10.98) and days to first female flower appearance (10.44 and 10.77), suggested existence of considerable variability in the population. Selection for these traits may also be given the importance for improvement programme. Similar findings were also reported earlier in bottle gourd by Munshi and Acharyya (2005), Gayen and Hossain (2006), Pandit *et al.* (2009), Bhardwaj *et al.* (2013), Sharma and Sengupta (2013) and Mangala *et al.* (2015).

In the present investigation high magnitude of heritability was recorded for all the characters under the study. The highest heritability was recorded for 100 seed weight (98.0%) and ascorbic acid content of the pulp (98.0%) followed by vine length (96.0%), average fruit weight (96.0%), fruit width (96.0%), fruit yield per plant (96.0%) and seed number per fruit (96.0%), days to first male flower appearance (95.0%), days to first female flower appearance (94.0%), days to first fruit harvest (94.0%), total sugar content of the pulp (94.0%) and number of fruits per plant (93.0%) and sex ratio (93.0%), number of primary branches (92.0%), fruit length (89.90%) and TSS of the pulp (86.0%). Similar high heritability for all the traits was also reported Munshi and Acharyya (2005) and Bhardwaj *et al.* (2013).

Genetic advance as percentage of mean was observed high for all the characters under the study *viz.*, fruit width (74.79%), fruit length

(74.03%), vine length (61.15%), fruit yield per plant (51.51%), sex ratio (46.12%), number of fruits per plant (44.44%), number of primary branches (43.02%), seed number per fruit (42.18%), average fruit weight (41.44%), 100 seed weight (27.86%), TSS of the pulp (27.00%), total sugar content of the pulp (26.69%), ascorbic acid content of the pulp (25.64%), days to first harvest (23.09%), days to first male flower appearance (21.43%) and days to first female flower appearance (20.83%).

Heritability estimates along with genetic advance are more useful than the heritability value alone for selecting the best individual. High heritability coupled with high genetic advance as percentage of mean was observed for vine length, number of primary branches, days to first male flower appearance, days to first female flower appearance, days to first harvest, number of fruits per plant, average fruit weight, fruit length, fruit width, fruit yield per plant, sex ratio, seed number per fruit, 100 seed weight, TSS of the pulp, total sugar content of the pulp and ascorbic acid content of the pulp indicated that these characters were mainly controlled by additive gene effects and thus selection may be rewarding for the further improvement of these traits. These findings are in general agreement with the findings of various workers in bottle gourd for various quantitative traits like, for vine length, number of primary branches and yield per plant by Bhardwaj *et al.* (2013); for all the characters studied by Sharma and Sengupta (2013); for days to first male flowering and female flowering by Husna *et al.* (2014); for node number at first female flower, sex ratio, fruit length, fruit girth, number of fruits per plant and fruit yield per plant by Mangala *et al.* (2015) and for total fruit yield per plant, number of primary branches, number of fruits per plant and average fruit weight by Aashish *et al.* (2016).

**Table.1** Different qualitative characters on plant morphology of 21 genotypes in bottle gourd

Sl. NO	Genotypes	Stem shape	Tendrill	Tendrill type	Tendrill branching	Leaf margin	Leaf shape	Sex type	Flower colour	Inflorescence type	Fruit shape	Fruit colour

11	Sex ratio (M/F)	5.20	12.16	7.81	3.50	3.27	23.96	23.16	93.00	3.60	46.12
12	Seed number per fruit	311.78	697.03	453.01	9250.95	8921.52	21.23	20.85	96.00	191.08	42.18
13	100 seed weight (g)	10.71	19.73	14.75	4.18	4.08	13.87	13.70	98.00	4.11	27.86
14	TSS of the pulp ( <sup>0</sup> Brix)	2.60	4.20	3.38	0.26	0.23	15.21	14.12	86.00	0.91	27.00
15	Total sugar (%)	1.38	3.04	2.60	0.13	0.12	13.75	13.35	94.00	0.69	26.69
16	Ascorbic acid (mg/100 g)	6.06	10.09	8.44	1.14	1.12	12.64	12.55	98.00	2.16	25.64

The present investigation revealed that the morphological characters are useful for characterizing genotypes against highly heritable and stable traits. Further, association of any qualitative character with desirable traits or yield components serves as a phenotypic marker in the selection process. On the basis of this study, it can be concluded that selection would be rewarding for fruit length, fruit width, vine length, fruit yield per plant, sex ratio, number of fruits per plant, number of primary branches, seed number per fruit and average fruit weight in bringing out the improvement in the bottle gourd because they appeared with high value of GCV, PCV, heritability and genetic gain.
