Bougainvillea antiviral protein (BAP) is one among a class of the ribosomal inactivating proteins isolated from *Bougainvillea spectabilis* Willd. Truncated version of the BAP gene was cloned and expressed in a prokaryotic vector to abolish its cytotoxicity. RNA was isolated from mature leaves of *Bougainvillea* and the full length cDNA was amplified by reverse transcription-PCR using template mRNA. This full length cDNA of size 756 bp was amplified using the proofreading polymerase (Q5 polymerase) and end to end gene specific primers for removal of C-terminal, the amplicon was cloned in pJET1.2l vector by blunt end cloning method. Restriction digestion was performed to release the fragment which was further ligated into prokaryotic expression vector pET29a. The recombinant plasmid was transferred into *E.coli* expression strain BL21 (DE3) and the truncated-BAP gene was expressed by isopropyl β -D thiogalactopyranoside (IPTG) induction. Transformed colonies expressed recombinant fusion *Bougainvillea* antiviral protein of molecular weight ~14.6 kDa, the size expected for the truncated BAP gene.

Introduction

Many of higher plants extracts reported to possess the antiviral properties shows the presence of certain substances of proteinaceous nature called as Antiviral proteins (AVPs). These AVPs have the property of inhibiting viral protein synthesis by inactivating the ribosomes. As a result, virus replication is inhibited. One such AVP, namely *Bougainvillea* Antiviral protein

(BAP) with ribosome inactivating property had been isolated from *Bougainvillea spectabilis* Willd. and characterized in our laboratory, previously. These antiviral proteins are categorized under ribosome inactivating proteins (RIPs). The genes encoding various AVPs have been isolated from many plants (Habuka *et al.*, 1989, Wu *et al.*, 1998, Cho *et al.*, 2000). These genes have been successfully introduced in plants and the transgenic plants expressing AVPs have also

been reported (Chen *et al.*, 2002, Wallalwar and Balasaraswathi, 2017).

Bougainvillea spectabilis Willd. is a flowering shrub classified under the family Nyctaginaceae. Earlier studies in our lab revealed that the crude extract was able to inhibit several tospoviruses viz., *Tomato Spotted Wilt Virus* (TSWV), *Tobacco Mosaic Virus* (TMV) and *Cucumber Mosaic Virus* (CMV) (Sadasivam *et al.*, 1991). The virus inhibiting factor was determined to be a protein termed, *Bougainvillea* Antiviral Protein (BAP). The protein was purified and characterized from *Bougainvillea spectabilis* roots (Balasaraswathi *et al.*, 1998). RIPs/AVPs can offer broad resistance against various virus species and may be a promising strategy to develop resistance against viruses (Wang and Tumer 1999, Zoubenko *et al.*, 2000, Wang and Hudak 2003, Vandebussche *et al.*, 2004). The present study was aimed to check the effect of C-terminal truncated BAP gene on cytotoxicity towards the expressing host cell.

Materials and Methods

Plant material

Fresh, tender leaves samples from *Bougainvillea spectabilis* (Non host plants) was collected from Botanical Garden, Tamil Nadu Agricultural University, Coimbatore. Various strains of *E. coli* like DH5 α and BL21 (DE3) were used for cloning and gene expression, respectively.

Isolation and cloning of truncated BAP-cDNA

Total RNA was extracted from fresh, tender (100 mg) leaves of *Bougainvillea spectabilis* Willd. using total RNA isolation kit (Sigma Aldrich). cDNA synthesis was carried out by using a commercial kit (Revert Aid First

Strand cDNA Kit, Vilnius, Thermo-Fermantas -Lithuania). The truncated *Bougainvillea* antiviral protein gene was isolated by PCR amplification. The gene specific primers were designed for the amplification of full-length bouganin gene based on registered sequences in GenBank (GenBank access number AF445416) using Vector NTI Software. The following PCR cycle was used to amplify the truncated BAP gene: denaturation at 98 °C for 3 min, followed by 35 cycles of 98°C for 30 Sec, annealing at 57 °C for 45 sec and an extension of 72 °C for 40 sec, with a final extension of 72 °C for 5 min. A 20 μ L of PCR mixture contained; 1 μ L of each primer (100 pm(AJ784781.1ol), 10 μ L of 2X Q5 polymerase (High Fidelity Polymerase) master mix (NEB, England), 1 μ L of cDNA, and 7 μ L of DNase free water. The amplified DNA was electrophoresed in 1% agarose gel and the remaining product was purified using a PCR clean-up kit (Biobasic Canada Inc. kit) and directly used for blunt end cloning in pJET1.2 vector having ampicillin resistance as a selectable marker (pJET Cloning Kit, ThermoScientific). *E. coli* DH5 α competent cells were used to transform the clone and recombinant colonies were checked by using colony PCR and restriction digestion (Fig. 1) and the confirmation of positive clone was done by sequencing at Agrigenome Pvt. Ltd., Bengaluru.

Nucleotide sequences were deduced into Amino acid sequences using translate tool in the ExPASy (Expert Protein Analysis System) server. Sequence alignment was carried out using BioEdit software tool (Hall 1999) with amino acid sequences of other antiviral/ribosome inactivating protein producing plants. MEGA X software tool was used to construct the phylogenetic tree by neighbour-joining method (Kumar *et al.*, 2018).

Construction of vector for inducible *in vitro* expression of truncated BAP gene

The eluted product was cloned into the expression vector pET29a between *XbaI* and *XhoI* restriction sites located at multiple cloning site of pJET1.2 vector. The digestion reaction mixture (50 μ l) contained; 12 μ l of 300 ng pJET1.2 vector containing truncated BAP gene, 2 μ l Cutsmart buffer, 1 μ l of each *XbaI* and *XhoI* and 34 μ l of nuclease free water and kept for incubation at 37°C for 1 hour. The digested product was electrophoresed in 1% agarose gel. DNA bands were purified using a gel extraction kit (Biobasic Canada Inc. kit) and using ligation kit, eluted gene was cloned into the pET29a expression vector (Sambrook *et al.*, 1989). *E. coli* DH5 α competent cells were used to transform the clone and recombinant colonies were checked by colony PCR and restriction digestion (Fig. 2) and the confirmation of positive clone was done by sequencing at Agrigenome Pvt. Ltd., Bengaluru.

Expression and purification of recombinant truncated *Bougainvillea* antiviral protein pET29-BAP-C

The plasmid from the positive clone was used for transformation of expression strain BL21 (DE3) cells for protein expression through IPTG induction. *XbaI* and *XhoI* sites of pET29a vector containing 6X His Tag coding sequence were used to produce the recombinant plasmid. Then, recombinant plasmids harbouring the truncated BAP gene were transformed into competent cells of *E. coli* BL21(DE3) using heat shock method. Luria-Bertani (LB) broth containing kanamycin was used to grow transformed cells at 37°C overnight. Truncated BAP gene bearing clones were determined by colony-PCR and by restriction digestion. Positive clone identified was grown on LB broth to OD₆₀₀ 0.6. With a consistent shaking for

overnight at 37°C, the bacterial growth was stimulated by adding 10 mM IPTG at different time intervals. The growth media was centrifuged and the bacterial cells were pelleted and resuspended with lysate buffer, suspension was sonicated five times (5s) with gap of 5s in ice then kept the mixture for incubation on ice for 35 min. After that protein extract was spin at 10,000 rpm for 15 min (4°C). The pellet was resuspended in 10% SDS and denatured at 80°C for 3min. and the protein profile was analyzed by SDS-PAGE.

Results and Discussion

Cloning of truncated *Bougainvillea* antiviral protein gene

The RT-PCR result revealed that only one specific DNA band of ~750 bp in length, was visualized in agarose gel electrophoresis. After cloning in pJET1.2 vector, the gene was sub-cloned in pET29a expression vector. The purified recombinant plasmids were then sequenced bidirectionally to verify the authenticity of the amplicon. The sequencing report showed that truncated BAP gene of size 756 bp shared 84.75 % identity with other isoforms of BAP sequences from *Bougainvillea* species. The truncated BAP gene was translated into amino acid sequence and has an initiation amino acid methionine (ATG), and terminated by histidine amino acid (CAC). The truncated BAP gene contained a complete open reading frame and had no introns.

***In-silico* analysis of cDNA encoding truncated BAP gene**

The nucleotide composition of the cDNA as analyzed by the Bio Edit software was found to be: 207 Adenine (27%), 231 Thymine (32%), 172 Cytosine (22%), 146 Guanine (19%) and the total G + C and A + T content

was 59% and 41 % respectively. Thus, based on the nucleotide composition the isolated cDNA was found to be AT rich. A BLAST N search did not show any significant homology of the truncated BAP- cDNA with other known sequences of RIPs/ AVPs from other plants, except 84.75% and 82.99% homology with cDNA encoding the AVP of roots (Ap1)

and leaves (Bouganin) of *Bougainvillea spectabilis*, respectively (Altschul *et al.*, 1997). However, Clustal W alignment with different RIPs/AVPs showed a strong homology with the nucleotide sequences of antiviral/ribosome-inactivating protein AAP1 (AY354205.1) and p-1 gene (AJ784781.1) (results not shown).

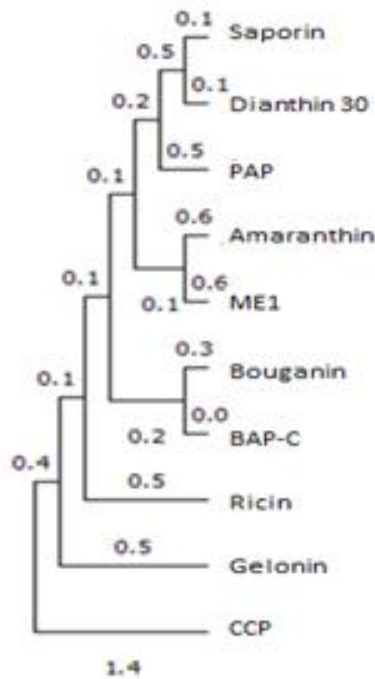

Fig.4 Phylogenetic relationship of BAP-C to different RIPs. The deduced amino acid sequence of BAP-C, Saprin (CAA41948.1), Bouganin (AAL35962.1), PAP (CAA66702.1), ME1 (AAN65450.1), Amaranthin (AAD09240.1), Ricin (1OBT), Gelonin (sp|P33186.2), Dianthin (1RL0), CCP (CAH04896.1)

Fig.5 Expression pET-BAP-C in *E. coli* BL21 (DE3) expression system
The figures shows samples from host cells BL21 uninduced (Lane 1), pET-BAP-C uninduced (Lane 2), BL21 induced (Lane 3) and pET-BAP-C induced ~ 14.6 kDa truncated BAP (Lane 4).
Markers are given in lane M. (Molecular masses in kDa)

The truncated BAP-cDNA was translated (www.expasy.com) and deduced amino acids are presented in (Fig. 3). It was found that the ORF of 756 bp encodes 130 amino acid residues. The amino acid composition was checked using the ProtParam tool and shows that the protein is rich in Alanine and Leucine (9.2%), followed by Valine (8.5%) and Asparagine (7.7%). The molecular weight of the protein was predicted to be 14.6 kDa. The BLASTP ORF-encoded amino acid sequence of BAP showed an identity with different RIPs/AVPs, being maximum with both *Bougainvillea* antiviral protein and bouganin. Conserved domains were searched with CDD search tool as well as the ClustalW alignment and it was found that the truncated protein showing strong homology with RIP superfamily (cl08249) and amino acid sequences of other RIPs respectively (Fig. 3). The phylogenetic relationship of deduced amino acid sequence of truncated BAP with ten other RIPs/AVPs constructed on the basis of ClustalW alignment is shown in (Fig. 4). The truncated BAP-C and bouganin proteins could be grouped into one cluster with highest bootstrap values. This may be due to the fact that all these AVPs are from two species of *Bougainvillea* only. The truncated BAP-C cluster was also related to other clusters of AVPs (ME1 and Amaranthin). This may be due to the fact that BAP and ME1 except Amaranthin belong to the same family Nyctaginaceae. While with PAP, Dianthin, Saporin observed a distant relationship of the BAP cluster and there was no relation found with Ricin, Gelonin and CCP.

SDS- PAGE analysis of recombinant truncated-BAP

The pET29a/BAP-C transformed into *E.coli* BL21 (DE3) strain, the recombinant protein expressed was induced by IPTG at fixed time intervals. After induction, cells were lysed and the expression profiles of protein

compared by SDS-PAGE. Purity of eluted fractions was pertinent and showed a prominent band of ~ 14.6 kDa to that of fused truncated BAP in case of pET-BAP, whereas there was no distinct band of that size in pET29a control and change in expression of recombinant protein increases after the induction with IPTG (Fig. 5).

Ribosome-inactivating proteins (RIP) have been sharing the property of depurinating the ribosomes irreversibly by catalytic i.e. enzymatic manner (Stirpe 2004). Although diverse studies in ribosomal inactivating proteins were carried out, to know the antiviral mechanism but the actual biochemical function is yet to be understood. Expression levels of RIPs in various plants is enhanced due to infection, other abiotic stresses like salinity, cold and post treatment like jasmonic acids, abscisic acid and mechanical wounding (Reinbothe *et al.*, 1994, Girbes *et al.*, 1996, Rippmann *et al.*, 1997, Song *et al.*, 2000, Iglesias *et al.*, 2008, Tartarini *et al.*, 2010). The gene encoding for BAP was isolated cloned and sequenced (Vipul, 2003). But the *E.coli* cells grew slowly and putative transformants generated were becoming necrotic even during the callus stage. This may be due to its cytotoxicity to host ribosomes. The cytotoxicity of pokeweed antiviral protein (PAP) was reduced by engineering the corresponding gene by removal of few base pairs from C-terminal (Tumer *et al.*, 1997). Hence, by truncating the BAP-cDNA, the cytotoxicity to the host could be reduced/removed while the antiviral activity is retained. So to reduce the cytotoxicity, the gene truncated at the C-terminal was cloned and normal growth of transgenic calli and transformants was observed. For the cloning and expression of recombinant proteins produced by the target gene in *E. coli*, pET expression system is the most powerful system. In this system, strong bacteriophage

T7 signals with transcriptional/translational control drives the target genes cloned; by providing T7 RNA polymerase source in the host cell which induces gene expression so that when there is full induction and conversion of almost all of the cell's resources to target gene expression and within a few hours after induction the desired product accounts for about more than 50% of the total cell protein (Novagen 2002). A 756 bp of truncated *BAP-C* gene cloned and expressed in pET29a/ BL21 (DE3) system and has shown truncated BAP of mass~ 14.6 kDa.

Truncated BAP gene was overexpressed in tomato plants to produce resistance against tospoviruses (Wallalwar and Balasaraswathi 2017). Antioxidant activity CCP and BAP was reported (Gholizadeh *et al.*, 2004, Bhatia *et al.*, 2004). The results can be utilized for expressing the truncated *BAP* in transgenic plants for evolving virus resistance. The overexpression of these antiviral/RIP genes in transgenic studies could be interesting and will be effective in better understanding of the physiological functions of different stress-related defense genes.
