Developed rotary weeder cum fertilizer drill was operated by the mini-tractor using three-point linkage, it performs both the operations of intercultivation and fertilizer application at a time. Experiments were conducted in field by varying forward speed ranged 1.8-2.0 kmh⁻¹, 2.5-2.7 kmh⁻¹ and 3.0-3.2 km h⁻¹. Calibration of the machine was conducted at laboratory condition and at field condition. A 42.67 % more fertilizer was dropped at field calibration on comparing with that of fertilizer dropped at laboratory calibration. The highest effective field capacity of developed machine was found out as 304×10⁻³ hah⁻¹ at the forward speed of 3.0-3.2 km h⁻¹. The highest field efficiency, highest weeding efficiency and lowest plant damage of developed machine were obtained at 1.8-2.0 km h⁻¹ forward speed of operation. The highest field efficiency, highest weeding efficiency and lowest plant damage of developed machine obtained were 86 %, 91.23 % and 3.62 % respectively. The lowest fuel consumption of developed machine was obtained as 1.30 lh⁻¹ at 1.8-2.0 km h⁻¹ forward speed.

Introduction

Weed growth is not stopped at a critical time, it results massive crop loss in crop production. Weeds decrease crop yields from 15 to 50% depending on the species, density and weeding time through competition with main crop for light, water and nutrition (Hasanuzzaman *et al.*, 2009). Delay in fertilizer application suppresses the crop vegetative development which leads to reduced yield. Research has shown that fertilizer input contributes about 30–50% of total yield increase for most of the crops

(Stewart *et al.*, 2005). Various methods used to control the weeds are manual weeding, cultural, mechanical, biological and chemical methods. In all these methods the most profitable and friendly is mechanical weeding because it is less polluting the soil and affordable on comparing with other methods.

Different fertilizer application methods are broadcasting, deep placement, foliar spray, fertigation, band placement, pellet application etc. In normal broadcasting and applying fertilizer on surface the nitrogen content in the granular fertilizer may undergoes

volatilization which leads to loss of fertilizer (Black *et al.*, 1985). It is better to adopt appropriate deep placement method of application to reduce the fertilizer losses. By adopting mechanization in the required areas of agriculture, timely operations with reduced drudgery and cost of cultivation can be achieved. It becomes effective with using rotary weeder combining with fertilizer application unit. To achieve timeliness and effectiveness in both the operations a mini tractor operated rotary weeder cum fertilizer drill was designed and developed. Mini tractor operated rotary weeder cum fertilizer drill was developed for wide spaced crops like castor, cotton and pigeon pea.

Materials and Methods

Mini tractor operated rotary weeder cum fertilizer drill was designed and developed at the Department of Farm Machinery and Power Engineering, College of Agricultural Engineering and Technology, Junagadh Agricultural University, Junagadh.

The major components of the machine include the frame unit, skid unit, rotary unit with L type blades, reversible shovel furrow openers, power transmission system, fertilizer hopper, Edge cell type metering rotors, fertilizer conveying system and ground wheel. Bevel gears, chains and sprockets were used in power transmission systems. The overall dimensions of the machine length \times width \times height of the machine were 1050 \times 1460 \times 1240 mm. The width of coverage of implement was designed for 1.2 m row crops. Performance of developed machine was evaluated through laboratory experiments and field experiments. The laboratory experiments conducted at the Department of Farm Machinery and Power Engineering. Field experiments conducted at Instructional farm, College of Agricultural Engineering and Technology, JAU, Junagadh.

Laboratory calibration

Calibration of the machine was done in the laboratory to examine the fertilizer delivery rate by keeping machine stationary. Rotary weeder cum fertilizer drill jacked up, made 20 revolution of ground wheel and fertilizer delivered was measured. Fertilizer dropping rate obtained at different hopper capacities, different ground wheel speeds and different door openings when the machine was stationary. This test repeated for 3 times for each full, $\frac{3}{4}$, $\frac{1}{2}$ and $\frac{1}{4}$ hopper filling capacities, different speeds of 1.8 to 2.0, 2.5 to 2.7 and 3.0 to 3.2 km h⁻¹ and different door openings of 30%, 40%, 60% and 100% of hopper (IS-6316:1993).

Field calibration

Calibration of machine was also done at field condition to know the variation of fertilizer delivered. During working of the machine fertilizer delivery tubes were removed from the furrow opener boots and separate sacks were held under them to collect the fertilizer.

During field calibration the rate setting which gave recommended dose of fertilizer at the time of laboratory calibration (40 % door opening) was used. It was done by operating the machine, allowing it to complete 20 revolutions ground wheel in field and the amount of fertilizer dropped calculated on hectare basis (*i.e.* kg ha⁻¹).

Performance evaluation of mini tractor operated rotary weeder cum fertilizer drill

Performance evaluation of developed machine was conducted through the two weeding cum fertilizer application operations in the castor field. First weeding operation was done after the 30 days of sowing day and second weeding operation was done after the 45 days of sowing day. During its

performance evaluation soil parameters, operating parameters and performance parameters was determined.

Performance of the implement evaluated by determining effective field capacity, field efficiency, weeding efficiency, plant damage and fuel consumption.

Experimental design

The field data were statistically analyzed by using analysis of variance (ANOVA) for Completely Randomized Design (CRD) with six replications. Details of experimental plot are shown in Table 1.

Soil condition

Soil type

Castor crop was grown in clay soil which consisted of 42.8% clay, 35.8% silt and 20.4% sand portions.

Soil moisture content (%)

Moisture content of the soil determined by standard gravimetric method. Five soil samples taken from the different locations at 10 cm depth of the test plots in different moisture boxes and kept in oven for 24 hours at the temperature of 105⁰C. The mass of wet and dry samples determined and average moisture content on dry basis was calculated (IS: 2720-2-1973).

$$\text{Moisture Content (d.b.)\%} = \frac{W_w - W_d}{W_d} \times 100 \quad (1)$$

Where;

W_w = Weight of the wet soil, g

W_d = Weight of the dry soil, g

Bulk density of soil

Metallic core cylinder used to collect soil sample from the field. Five samples taken in 100 mm diameter and 128 mm long core sampler. The samples weighed with an accuracy of 0.1 gram. The ratio of the dry weight of the soil to the volume gives the bulk density (Punmia *et al.*, 2009).

$$\text{Bulk density of soil (g/cc)} = \frac{W_d}{V} \quad (2)$$

Where,

W_d = Weight of the dry soil, g

V = Volume of metallic core, cm³

Crop condition

Developed rotary weeder cum fertilizer drill was operated in a castor crop of 120 x 60 cm row to row and plant spacing. At the time of first weeding operation the plant height of crop varied from 16 to 24 cm. At the time of second weeding operation the plant height of crop varied from 40 to 53.5 cm.

Measurements of different parameters

Forward speed

Performance of mini tractor operated rotary weeder cum fertilizer drill evaluated at three different forward speeds (1.8-2.0, 2.5-2.7 and 3.0-3.2 kmh⁻¹).

The forward speed calculated for the mini tractor by observing the time (t) taken to travel 20 m row length of test plot. The forward speed of operation was calculated by following formula.

$$S = \frac{L}{t} \quad (3)$$

S = forward speed of machine, ms⁻¹

L = distance travelled, m

t = time taken, s

Depth of weeding

The depth of cut for rotary blade assembly in weeding operation determined by measuring the distance between horizontal soil surfaces to the bottom of dug out pulverized soil with the help of depth gauge.

Depth of fertilizer application

Depth of fertilizer drilled measured by opening the furrow gently without much disturbing the soil and measured the depth of fertilizer in soil with the help of steel scale.

Wheel slip

Number of revolutions counted for certain distance of operation for loading and unloading condition. Wheel slippage of mini tractor calculated by using following formula. (IS: 17045-2018).

$$\text{Percentage of wheel slip} = \frac{(P-Q)}{P} \times 100 \quad (4)$$

Where,

P= No. of revolution of driving wheels made for a 20 m distance when the tractor was driven under load,

Q= No. of revolutions of driving wheels made for a 20 m distance when tractor was driven without load.

Theoretical field capacity

It was the rate of area covered without loss of time. It was calculated by using following formula (Kepner *et al.*, 2005).

$$\text{Theoretical field capacity} \left(\frac{\text{ha}}{\text{h}} \right) = \frac{\text{Width of coverage (m)} \times \text{Speed} \left(\frac{\text{km}}{\text{h}} \right)}{10} \quad (5)$$

Effective field capacity

It was the actual rate of work which includes the time lost in turning at the end of rows and refilling of fertilizer. It was calculated by using following formula (Kepner *et al.*, 2005)

$$\text{Effective field capacity} \left(\frac{\text{ha}}{\text{h}} \right) = \frac{\text{Width of coverage (m)} \times \text{Length of strip (m)}}{\text{Time taken (h)} \times 10,000} \quad (6)$$

Field efficiency

Field efficiency defined as the percentage of time the machine operates at its full rated speed and width while in the field. It was calculated by using following formula (Kepner *et al.*, 2005)

$$\text{Field efficiency (\%)} = \frac{\text{Effective field capacity}}{\text{Theoretical field capacity}} \times 100 \quad (7)$$

Plant damage

Number of plants present before the weeding (p) counted in a 10 m row. After the weeding no. of plants damaged (q) counted for the same row length. Plant damage was calculated with the help of following formula. (Vala *et al.*, 2019)

$$\text{Plant damage (\%)} = \frac{q}{p} \times 100 \quad (8)$$

Weeding efficiency

Weeds present before and after the weeding operation counted to calculate weeding efficiency. Weeding efficiency calculated with the help of following formula. (Rathod *et al.*, 2010)

$$\text{Weeding efficiency (\%)} = \frac{X-Y}{X} \times 100 \quad (9)$$

Where,

X= No. of weeds before operation per m² area
Y= No. of weeds after operation per m² area

Fuel consumption

The fuel consumption of mini tractor operated rotary weeder cum fertilizer drill measured as per the standard prescribed method. The auxiliary tank attached at fuel system in between fuel tank and engine. The time of operation by mini tractor and fuel consumed in auxiliary tank were recorded. Fuel consumption of mini tractor was determined by dividing the fuel consumed to the time of operation.

Operational energy for mini tractor operated rotary weeder cum fertilizer drill

Energy consumption for weeding and fertilizer application calculated by standard energy consumption for tractor in MJh^{-1} . Energy utilized by mini tractor operated rotary weeder evaluated by the following formula (Umar, 2003).

$$E_f = 47.78 D \quad (10)$$

Where,

E_f = Fuel (diesel) energy expended, MJh^{-1}
47.78 = Unit energy value of diesel, MJL^{-1}
D = Amount of fuel (diesel) consumed, lh^{-1} .

Results and Discussion

Laboratory calibration

Granular urea fertilizer was used in laboratory calibration.

The required fertilizer rate (40 kg ha^{-1}) noticed at the 40 % door opening of hopper during stationary calibration. The fertilizer rate was adjustable from 29 kg to 170 kg per hectare by using this machine. The variation in dropping of fertilizer in between two furrow openers ranged from -0.54 % to 5.98 %. The variation in dropping of fertilizer due to box filling at 1/4, 1/2, 3/4 and full capacity of hopper ranged from -4.24 % to 4.30 %. The variations in quantities of fertilizer dropping

due to change in speeds from $1.8\text{-}2.0 \text{ kmh}^{-1}$ to $3.0\text{-}3.2 \text{ kmh}^{-1}$ speeds were ranged from -5.56 % to 5.23 % (Fig. 1–10 and Table 1–10).

Effect of hopper filling and door opening on fertilizer delivery rate

Fertilizer delivery rate was increased with increased door opening of hopper at all levels of hopper. Fertilizer delivery rate increased from $1/4$ capacity of hopper filling to full capacity of hopper filling.

Effect of forward speed of operation on fertilizer delivery rate

Fertilizer drill was operated at 40% hopper opening and different speeds by changing the rotational speed of ground wheel to know the variation in fertilizer delivery rates. On increasing the speed of operation, the fertilizer delivery rate was decreased at all levels of hopper. At higher speeds of metering rotor spilling of fertilizer occurs and results less delivery of fertilizer.

Field Calibration

On increasing the forward speed of operation from $1.8\text{-}2.0 \text{ kmh}^{-1}$ to $3.0\text{-}3.2 \text{ kmh}^{-1}$ speed the fertilizer delivery rate was also decreased in field condition. At field condition because of continuous vibrations from the rotary shaft assembly there was a more dropping of fertilizer from hopper to metering mechanism and then to crop through delivery tubes. More fertilizer was dropped at field condition on comparing with that of the fertilizer dropped at laboratory condition by using same rate setting (40 % door opening area of hopper). Variations in fertilizer delivered at field condition and laboratory condition were ranged from 40.66 % to 44.51. An average variation of 42.67 % was noticed in the study. By using the reduced rate setting (30 % door opening area of hopper) the required fertilizer

delivery rate (40 kg ha^{-1}) was obtained at field condition.

Soil moisture content

At the time of first performance evaluation the average moisture content was found to be 27.56 % on dry basis and at second performance evaluation the average moisture content was found to be 20.86 % on dry basis.

Bulk density of soil

The bulk density of the soil at the time of first performance evaluation was found to be 1.52 gcc^{-1} in the test plot and at second performance evaluation the bulk density of 1.46 gcc^{-1} was found in the test plot. Bulk density of soil was decreased by a little amount due to the thorough pulverization at first weeding operation resulted in increased voids in soil.

Depth of weeding

Depth of cut observed at first weeding was slightly greater than that of second weeding at all the forward speeds during performance evaluation. It was obtained because of more soil moisture content in the field at the time of first weeding operation as compare to the weeding operation.

At higher speeds the depth of cut decreased due to reduced time of contact of blades with the soil in both the weeding operations.

Depth of fertilizer application

Depth of fertilizer application observed at first weeding and second weeding operations was almost same during performance evaluation. At higher speeds the depth of fertilizer application decreased to little extent at both the weeding operations.

Wheel slip

At the time of first weeding operation the amount of wheel slip was obtained as -2.53 %. During second weeding operation the amount of wheel slip was obtained as -3.85 %. Wheel slip found at second weeding operation was less than that of first weeding operation because of less moisture content in the field during second weeding operation.

Effect of forward speed on effective field capacity

Effective field capacity obtained during both the operations increased by increasing the forward speed from $1.8\text{-}2.0 \text{ kmh}^{-1}$ to $3.0\text{-}3.2 \text{ kmh}^{-1}$. The observations obtained for effective field capacity at the time of first weeding and second weeding were statistically highly significant because by varying the forward speed of operation the effective field capacity also varied widely in the field.

Effective field capacity observed at first weeding operation was slightly greater than that of second weeding operation at all the forward speeds during performance evaluation. It was observed that time losses were more at the time of second weeding operation because of more spread of plants in field.

Effect of forward speed on field efficiency

During the first weeding operation, the field efficiency was decreased by increasing the forward speed from $1.8\text{-}2.0 \text{ kmh}^{-1}$ to $3.0\text{-}3.2 \text{ kmh}^{-1}$ speed. At the second weeding operation the field efficiency was slightly varied by changing the forward speed from $1.8\text{-}2.0 \text{ kmh}^{-1}$ to $3.0\text{-}3.2 \text{ kmh}^{-1}$ speed. The measurements obtained for field efficiency for both the weeding operations were statistically non-significant because the time losses obtained for different experiments were not varied much in performance evaluation.

Table.1 Details of experiment

Sr. No.	Variables	Parameter	Levels
1.	Independent parameters	Forward Speed	1.8-2.0km h ⁻¹

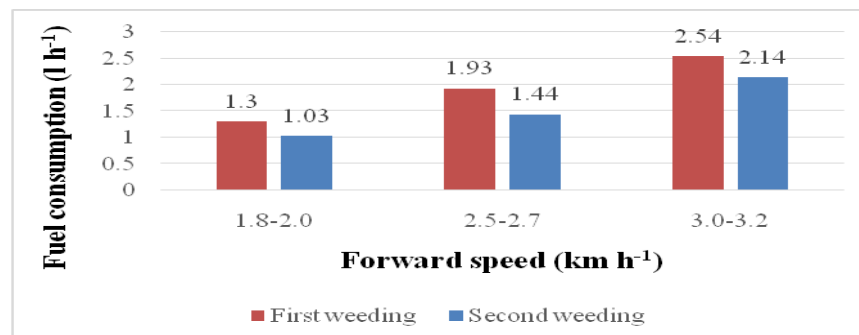

Plate.1 Field Calibration

Plate.2 Field view of rotary weeder cum fertilizer drill

Field efficiency observed at first weeding operation was greater than that of second weeding operation at all the forward speeds during performance evaluation.

Effect of forward speed on plant damage

Plant damage obtained during both the operations increased by increasing the forward speed from 1.8-2.0 kmh⁻¹ to 3.0-3.2 kmh⁻¹. The results obtained for plant damage in first weeding are statistically non-significant. Plant damage was almost same in less grown crop in the field at the time of first weeding. The results obtained for plant damage in second weeding are statistically highly significant because of more plant damage at higher speeds.

Plant damage observed at second weeding operation was more on comparing with the plant damage observed at first weeding

operation at all the speeds. This was because of more growth and spread of plants in the field during second weeding operation.

Effect of forward speed on weeding efficiency

Weeding efficiency obtained during both the operations decreased by increasing the forward speed from 1.8-2.0 km h⁻¹ to 3.0-3.2 kmh⁻¹. The observations obtained for Weeding efficiency at the time of first weeding and second weeding were statistically highly significant because by varying the forward speed of operation the Weeding efficiency also varied widely in the field during performance evaluation.

Weeding efficiency observed at first weeding operation was more on comparing with the weeding efficiency observed at second weeding operation at all the speeds. It was

because of more number of weeds per unit area of test plot before weeding operation at the time of first weeding operation on comparing with that of the second weeding operation.

Fuel consumption

Fuel consumption obtained during both the operations increased by increasing the forward speed from 1.8-2.0 kmh⁻¹ to 3.0-3.2 km h⁻¹. At the time of first weeding operation the fuel consumption observed at 1.8-2.0 kmh⁻¹, 2.5-2.7 kmh⁻¹ and 3.0-3.2 kmh⁻¹ speeds was 1.30, 1.93 and 2.54 l h⁻¹ respectively. During second weeding operation the fuel consumption observed at 1.8-2.0 kmh⁻¹, 2.5-2.7 kmh⁻¹ and 3.0-3.2 kmh⁻¹ speeds was 1.03, 1.44 and 2.14 hah⁻¹ respectively. Fuel consumption observed at first weeding operation was more on comparison with the fuel consumption observed at second weeding operation at all the speeds.

Operational energy for mini tractor operated rotary weeder cum fertilizer drill

The energy spent for weeding operation at 1.8-2.0 kmh⁻¹ speed during performance evaluation was $E_f = 47.78 \times 1.3 = 62.12 \text{ MJh}^{-1}$.

In conclusion the highest effective field capacity of developed rotary weeder cum fertilizer drill was found as $304 \times 10^{-3} \text{ hah}^{-1}$ at the forward speed of 3.0-3.2 kmh⁻¹. The highest field efficiency of developed machine was obtained as 86 % at forward speed of 1.8-2.0 kmh⁻¹. The highest weeding efficiency of developed machine was obtained as 91.23 % at forward speed of 1.8-2.0 kmh⁻¹. Lowest plant damage of developed machine was obtained as 3.62 % at 1.8-2.0 kmh⁻¹. The lowest fuel consumption of developed machine was obtained as 1.03 l h⁻¹ at 1.8-2.0 kmh⁻¹. In fertilizer delivery rates of laboratory calibration and field calibration an average variation of 42.67% was noticed in the study.
